ABSTRACT

Goitrogenic substances can inhibit iodine taking by the thyroid gland. Thus iodine concentration in thyroid gland will be low, and this phenomena is indicated by inflammation in the thyroid gland. Moreover, it can cause releasing of an excessive amount of free radicals. This radicals, in the body, causes oxidative stress and also increase the levels of malondialdehyde (MDA). This is also as an indicator for lipid peroxidation and the decreasing of urinary iodine excretion levels (EIU). The treatment with KIO₃ and KI salt was intended to study the level of supplementation of iodine (I₂) toward level of MDA in serum and histological description of rat’s thyroid gland. The MDA levels was determined through TBA test (Thio Barbituric Acid), meanwhile the histological pattern of rat thyroid gland was determined by Hematoxylen-Eosin staining (HE). The results indicated both of KIO₃ and KI salt significantly (p<0.01) reduced MDA level in the serum. Treatment with KIO₃ salt gave 33.62% while KI salt slightly higher (37.02%). In addition, both of treatments displayed an recovering effect in thyroid gland.

Key word: Goitrogenic, Iodium, Malondialdehyde, KIO₃ and KI salt therapy.

INTRODUCTION

Recent National Survey in Indonesia (1998) reported 53.8 million people live with iodine deficiency risk, 20 million suffer from goitre, 290 thousand estimated to suffer from creatine, and approximately 9 thousand infants born each year [1]. Thyroid disease in Americans country continuously growth, and approximately 17,000 cases occured each year, and about 1,700 of them resulting death. A study in England from Whickham Study of the United Kingdom reported that goitre is suffered in 16% from the total population by people. In the Framingham study reported that the ultrasound examination of thyroid nodules found in older men over 60 years at 3%, while for 48-year-old woman recorded at 36% [2]. In America, majority cases of thyroid goitre caused by autoimmune and known as Hashimoto's disease. But, mostly the cause of goiter is due to iodine deficiency. It is estimated that about 200 million goitre among the 800 million people suffering from iodine deficiency. Whickham study reported the prevalence of goiter 26% of women, compared to only 7% of men or women genders dominated by a ratio of 4: 1 [2].

A variegated goitrogenic can cause a disease in inflammation. While inflammation of the membrane in the gland thyroid (adipose) can be caused by cytokine pro-inflammation and high production of free radicals. This result is the onset of oxidative stress in which the
imbalance of radicals level in the body and lead to damaging of the cell membrane. This process can be identified by increasing of malondialdehid (MDA) level and other indicator for lipid peroxidation. Injecting or consuming of the antioxidant substances from outside the body can suppress elevation of MDA level in the body. Generally, treatment of iodine can affect by improving the level of iodine deficiency in the body. But, prolonged the iodine deficiency will interfere the process in formation of thyroid hormones. When the body has iodine deficiency, the concentration of thyroxine hormone in the blood is low. This condition stimulates the body to enhance the thyroid tissue. As a result is enlargement of thyroid gland, or is called a goiter [3]. Theoretically, therapy using substance contained iodine such as KIO₃ and KI salt can increase iodine level, and this can be monitored through urine iodine status, the iodine content in urine, lowering levels of malondialdehyde (MDA).

EXPERIMENT

Animal treatment

All conditions of experiment and handling of the animals were conducted following the protocols approved by Ethical Clearance Committee in Brawijaya University (238-KEP-UB). A number of 20 rats (*Rattus norvegicus*) (female, body weight 125-200 g) were housed at room temperature in the animal house. This was gently care in the Laboratory of Cellular and Molecular Biology, Mathematics and Sciences Faculty, Brawijaya University Malang and were exposed to alternate cycles for 12 h light and dark. The rats were divided into four group, a healthy group, goitrogenic group, goitrogenic group treated with KIO₃ salt and goitrogenic group treated with KI salt. The goitrogenic rats groups were sonde injected with 1.75 mL KSCN in mouth and incubated for 3, 6, 9, 12, and 15 days. Then after 7 days, the goitrogenic rats group for divided into group treated with the KIO₃ and the group treated with KI salt. A dose level given oral was 80 mg/Kg body weight (BW) for 14 days. After day 15, group of rats were dissected. Rats were killed by neck dislocation, and rat serum, urine and gland thyroid were taken. The sera were taken in abdomen section, heart. This was put into pakutener non-EDTA and left for three hours and centrifuged at 600 rpm for 15 min. This serum was further analyzed. Moreover, gland thyroid were also taken and the skin were slashed, and washed with 0.1% NaCl and immersed in 4% PFA for seven days.

Analysis of iodine level using Ceric Ammonium Sulfate (CAS) test

Urine samples 250 µg was pipetted and shaked up in a sealed test tube. Each of tube contain sample were added 0.75 mL of iodine. Ammonium persulfate 1.0 mL was also added. After that, all the sample tubes were heated in 91-98 °C for 60 min. The tubes were cooled down to room temperature, and 3.5 mL of arsenite (As₂O₃) was added followed by homogenization for 15 min. Then, 4.0 mL ceric ammonium sulfate was dropped in each tube and mixed for 15 to 30 second. Then, each tubes was analysed using UV-Vis spectrophotometer at 420 nm with interval time 30 second.

Analysis MDA levels using TBA test

The rats serum 100 µl in tube was added 550 µl aquadest, 100 µl TCA 100%, 250 µl HCl 1 N, and 100 µl Na-thio 1%. This mixture was homogenized with a vortex, centrifuged at 550 rpm for 15 min, and the supernatant was taken. The resulted solution was incubated in water bath at 100° C for 20 min, and left to room temperature and measured using UV-Vis spectrophotometer at 532 nm.
Histological analysis using Hematoxylen-Eosin (HE) staining method

A prepare of the rats thyroid gland was immersed in 1-3 xylol for 5 min, and was put into the various concentration of ethanol, from absolute ethanol 1-3, ethanol 95%, 80%, and 70% respectively for 5 min. This was soaked in aquadest for 5 min and put into hemotoxylen dyes for ± 10 min. Then, it was washed over flowing water for 30 min, and rinsed with aquadest before continued to coloring with eosin dye. Then, it was inserted to eosin alcohol for 5 min and soaked in the aquadest to release the excess of eosin. Moreover, in the dehydration process, the equipment was inserted in the graded ethanol 80%, 90%, and 95% to the 1-3 absolute of ethanol. Then, in the clearing process, it was completed by placing in the xylol 1, 2 and was further dried. The result preparate was mounted using entellan, and the dried and stained ultrathin sections were observed using a microscope (Olympus BX53) with a magnification of 100 times.

RESULTS AND DISCUSSION
Effect thiocyanate (KSCN) and level of iodium in urine

Direct observation from physical appearance of the treated rats indicated changing in the physiological bodies of rat suffering from goitre due to exposure to thiocyanate (KSCN). KSCN experimentally inhibits transportation of iodide ions in the body. Then, it will lower iodine content. Physical phenomena can be see also from mouse.

![Figure 1](image_url)

Figure 1. Normal rat (Healthy, A), rats exposed to KSCN (Goitrogenic, B), salt therapy rats with KIO3 (Therapy, C), and salt therapy KI rats (Therapy, D).

Little appearance changing was observed on treated rats (Figure 1). The changing was compared to healthy rat (A) as negative control, rat exposed with thiocyanate or rat with goitrogenic problem (B), goitrogenic rat got treatment with KIO3 (C), and goitrogenic rat got treatment with KI (D). Summary of the diagnosis was presented in Table 1.
The affect of treatment with KIO3 and KI salt toward quantity measured of iodine level on rat urine was summarised on Table 2. Iodine deficiency was observed on group of rats administered with thiocyanate. This was a goitrogenic rats or sick rats, and was applied as positive control. The iodine level on urine was recorded on 0.035 ± 0.022 ppm. This was lower level than that in healthy rat (negative control rat). It has iodine level on 0.180 ± 0.011 ppm. In addition, treatment of the goitrogenic rats with KIO3 salt slightly improved the iodine level on urine to 0.063 ± 0.008 ppm than that in sick rats. Indeed, for group rats treated with KI salt gave better improvement of iodine content. It reached to 0.081 ± 0.007 ppm. However, both therapy using KIO3 and KI salt still lower than iodine content on healthy rats (0.180 ± 0.011 ppm). In other word, for the treatment goitrogenic rat with KIO3 and KI salt, there were an lowering level of iodine level on urine compared to the healthy rat or the were improvement of iodine level of goitrogenic rats after treatment with KIO3 and KI salt. This result was also analysed using statistical method with significant level (p < 0.01), and it gave significant differency above 99% (Figure 2).

It was also common stated that the incidence of iodine deficiency can be caused by potassium thiocyanate (KSCN) which inhibit iodine uptake by thyroid gland to bind organic iodine such as monoiiodothyrosine and diiodothyrosine. Both are part of the triglobulin located in each cell. These cause severe competition between serum thiocyanate and thyroxine to bind it, as a result of an increasing in serum thyroxine [4]. Salt administration using KIO3 and KI in mice on groups of goitrogenic rats reduces the level of iodine transport barriers. The bounded iodine in KIO3 and KI salts are converted to iodide (I) during
hormogenesis, process in thyroid hormone. This can increase iodine, even thought cause inhibition of peroxide generation due to a increasing of I-intra-thyroidal content by supplementation of KIO₃ and KI salt. Treatment with KIO₃ and KI can also affect pituitary to work harder secreting TSH and stimulate the thyroid gland to producing more thyroid hormone. As as result initiation of thyroid hyperplasia and hypertrophy (goiter).

**Figure 2.** Comparison of the iodine level in urine of healthy rats (*Rattus norvegicus*), goitrogenic rats, and therapies rat with KIO₃ and KI salt.

**Levels of malondialdehyde (MDA) in rats serum**

Measurement of malondialdehyde concentration contained in serum of the treated groups of rat was tabulated in Table 3 and display as picture on Figure 3. It was recorded that treatment with injection of KIO₃ and KI salt in goitrogenic rat reduced the MDA concentration on serum. As an negative control, group of healthy rats have malondialdehyde level 2.820±0.014 ppm. It is normal MDA level on serum. However, for group of rat with goitrogenic disease has three fold much higher of MDA level. It was measured on 7.857 ± 0.041 ppm. Treatment with KIO₃ and KI salt on groups of goitrogenic rats indicated reduction of their MDA concentration. Treatment with KIO₃ give a slight reduction to 5.215 ± 0.146 ppm while treatment with KI salt gave much lower value. It was reached to 4.925 ± 0.095 ppm. Even though this concentration indicated reduction, however this concentration still much higher than that for group of healthy rats (2.820±0.014 ppm).

In other word, the MDA levels of rat serum (*Rattus norvegicus*) decreased after treatment with KIO₃ salt by 33.62% while treatment with KI reached to 37.02%. This decreasing level was caused by iodum content in KIO₃ and KI salt. This iodine activate the process of inhibition for transporting goitrogen thiocyanate (KSCN). Improvement number iodine in thyroid gland may also accelerate the activity of iodine in stimulating the secretion of thyroid hormone, triiodothyroxine (T₃) and thyroxine (T₄). This will increase TSH level in thyroid gland, and finally will reduce a tissue destruction in thyroid gland.
Moreover, reducing MDA level means inhibit the free radical substances. This inhibition mechanism correlate to process in lipid peroxidation by both salts of KIO₃ and KI salt as antioxidant agent which counter act the free radicals in body. Iodine content in KIO₃ and KI salt possibly was the responsible substance as antioxidant [5]. Malondialdehyde (MDA) which is the product of peroxidation as an indicator that a lipid disorder was occurring. Therefore, the high concentration of malondialdehyde in groups of goitrogenic rat serum was also an indication of the high levels of the adipose membrane tissue disorder.

Figure 4. Comparison of the histological features between normal saline treated rat and goitrogenic rat

Effect at KIO₃ and KI salt on the histological features

Treatment of KIO₃ and KI salt using dose of 80 mg/Kg BW theoretically can reduce the formation of thyroït. This is a compiler for building of the thyroid follicle wall. The affect of both salts is displayed histologically can be observed (Figure 4). For normal conditions, (Figure 4-A), healthy rat without exposure thiocyanate. The surface of thyroid gland seem good, flat and orderly. Thyroït which is compose of thyroid follicular wall constituent regular, normal lumen with HE staining give pink color. The parafollicular cell or cells located outside the thyroid follicles. It shows the condition of the thyroid histology in normal or healthy condition. Contrastly, histology for goitrogenic rat appear different (Figure 4-B), thyroid histological changing was observed. Thyroït was not in regular structure. It
did not surround the thyroid follicles. The feature was not clear between thyrosit and parafollicular cells or cells itself where the position of thyrosit and parafollicular follicles along both outside and inside of the follicle. This damage is caused by the formation panus section, thus increasing the production of free radicals. These free radicals trigger the formation of antibodies by modifying the protein aggregates that activate phagocytic cells to cause inflammation or injury. The formation of antibodies itself againsts the auto-antigens or antigens from infectious genes (including goiter factors), and that lead to formation of immune complexes and lead to complex and activation of phagocytic [8].

Figure 4. HE Staining results on Goitrogenic Thyroid Gland Rat (Healthy rat, A), rats exposed to goiter KSCN (Sick rat, B). Salt therapy rats with KIO₃ (Therapy, C), and salt therapy with KI (Therapy, D). (Picture was recorded in 100x magnification, and arrows indicate the occurrence of structural changes in thyroid follicel, lumen, thyrosit and parafollicular thyroid cell on treatment).

Histology appearance from the thyroid gland of the goitrogenic rat got treatment with KIO₃ and KI salt was displayed in Figure 4-C and D. Both picture gave features of thyrosit surrounded thyroid follicles. Compare to the previous image (A and B), the parathyroid cells and thyrosit inside the thyroid follicles was not bright, slight darker than that in healthy thyroid gland (Figure 4-A). Slight damage was still observed, but improvement is indicated compared to the thyroid gland from goitrogenic rat (Figure 4-B). This irregularity structures possibly due to autoimmune processes of the body. Immune responses in the body protect it to eliminate antigens into the body and this recognizes the thyroid proteins as auto-antigens. Then, recognized of auto-antigen cause T-cell proliferation and resulted the damage thyroid tissue. Pro-inflammatory cytokines include IL-1, IL-6 and IL-8 in the thyroid gland and
appears on the body's immune response (TNF-α, IFN-γ,) causing the macrophage-mediated cell destruction occurs as well [9] [10]. This tissue damage was observed during of apoptosis on thyroid cells. It was indicated by irregularity pattern of cells, and there was thyrosit and parathyroid cells in the same feature on the thyroid follicles.

**CONCLUSION**

Goitrogenic rats treated with KIO₃ and KI salt increase the levels of iodine (I). Treatment with KIO₃ increase to 44.44% while therapy with KI reach to 56.79%. Moreover, therapy with KIO₃ and KI in rats exposed goitrogenic (KSCN) also decrease the malondialdehyde (MDA) level to 33.62% and 37.02%, respectively. The histological features indicated improvement on goitrogenic rat gland thyroid after therapy with both substances.

**ACKNOWLEDGMENT**

The author would like to thank to Prof Dr Chanif Mahdi, MS who has been given the opportunity to be part of the research with KIO₃ and KI therapy for deficiency iodium in goitrogenic rats. The writer was also grateful to Dr. Akhmad Sabarudin and Dr Masruri who has assisted the completion of this manuscript.
